Author

```
Rui Diao diaorui1987@gmail.com
```

Requirement

```
OS: Linux
Compiler: g++
```

Compilation

```
Run "make", or "g++ clonify.cc --std=c++0x -02 -fopenmp -o clonify". It generates a binary file "clonify".
```

Usage

```
./clonify <input_file> <output_file>
Required arguments
input_file: a JSON file
output_file: a text output of clustering result
Optional arguments
-n <N>: processed number of sequences from the input_file
-m: print out some memory usage information
-f <output format>: specify the format of output
```

Examples

```
./clonify NBD4681.json test.out
./clonify NBD4681.json test.out -n 1000
./clonify NBD4681.json test.out -n 1000 -m
,/clonify NBD4681.json test.out -n 1000 -f seqs
```

Multithreading

```
The code is implemented with OpenMP.

Please make sure you put "-fopenmp" in compilation flags (already in Makefile).

The code uses all cpu cores for computation.
```

Distributed Computing

```
If multithreading is enough, please ignore this part.

Suppose we have one master computing node, and several slave computing nodes.

All computing nodes communicate with socket.

Run "make slave" or "g++ clonify.cc -DSLAVE --std=c++0x -02 -fopenmp -o slave". It generates a binary file "slave".
```

Put the binary file "clonify" to the master computing node.

Put the binary file "slave" to all the slave computing nodes.

Run "./slave <#port>" on all the slave computing nodes. For example, "./slave 8888".

Create a text file "SLAVES" on master computing node, under the same directory with the binary file "clonify". "SLAVES" specifies the IP and #port of every slave computing nodes. One line for one slave computing node.

Do not list master computing node in "SLAVES".

Do not list one IP twice in "SLAVES", because we already have multithreading for every computing node.

See "SLAVES.sample" for reference.

Run "./clonify <input_file> <output_file>" on the master computing node.
